

As someone who has sighted a rat, I want to use the (Rat app name) to file a rat sighting so the information can be made known.

Tasks:

- I. Create a rat report page a user can fill out.
- II. Connect report page to google maps to pinpoint where report is occurring.
- III. Allow report to be sent to database, distributing information appropriately.

Acceptance Scenarios:

GIVEN: A user wants to file a rat report, WHEN they open the map interface, THEN the google maps API should allow them to pick the location of their report.

GIVEN: A user wants to file a rat report, WHEN they input the requisite information and click Enter, THEN the Rat Report is sent to the database.

GIVEN: A user is sending a rat report, WHEN they send in data that matches a previous report, THEN the report is deemed irrelevant, and the user is notified.

Done Done:

- SQL Server connected to database of Rat information
- Individual rat reports can be accessed remotely after creation
- System works offline and sends rat reports as soon as network connectivity is regained.
